

Lab 12 | Snowflake CLI

Copyright © 2026 Innovation In Software Corporation. All rights reserved.

Time: 20-30 minutes | **Script:** 12-SnowflakeCLI-Lab.sql

Before you start: CLI is installed, your trial account was created in class, and SetUp/SCHEMA-SETUP-SCOTT.sql has been run. Download the SQL script to your computer. Use your class role and warehouse; examples use SYSADMIN and COMPUTE_WH.

1. Create and test a connection

```
snow connection add -n training
```

Run this in your local terminal. If training already exists, reuse it. Enter your account as organization-account, your username, role SYSADMIN, warehouse COMPUTE_WH, database DEMO_DB, and schema SCOTT. For a standard trial account, leave **host** blank. Use the authentication settings confirmed with the instructor and complete MFA when required.

The wizard can save a password in plain text. Keep credentials local and never commit them to Git. To avoid saving a password, leave it blank and supply it for this terminal session using the instructor-approved method.

```
snow connection test -c training
```

Check: the test succeeds. **-c** selects a saved connection; training is its local name.

2. Use interactive SQL

```
snow sql -c training
```

At the SQL prompt, enter these statements. End each statement with a semicolon:

```
SELECT CURRENT_USER(), CURRENT_ROLE(), CURRENT_WAREHOUSE();  
SELECT DEPTNO, DNAME, LOC FROM DEMO_DB.SCOTT.DEPT ORDER BY DEPTNO;
```

Check: the first query identifies your session; the second returns four departments. To return to your terminal, type:

```
exit
```

3. Run a SQL file

In your terminal, change to the local folder containing the downloaded script, then run:

```
snow sql -c training -f "12-SnowflakeCLI-Lab.sql"
```

-f reads a local SQL file. Check the session information, department rows, and department count. Each CLI invocation can open a new session; the script sets its context explicitly.

4. Locate your connection settings

```
snow --info
```

Find **default_config_file_path** and open that file locally. In config.toml the profile is under **[connections.training]**. If connections.toml exists beside it, profiles are read from that file instead, under **[training]**. Do not share configuration files containing passwords.

Student Assignment

Complete the following using your existing trial account. You do not need another Snowflake account.

1. Create a new connection named **student_lab**. Set the class role and warehouse, database DEMO_DB, and schema SCOTT. Configure authentication for this profile as well; a password variable specific to training does not automatically apply to student_lab.
2. Test the new connection and start an interactive SQL session using it.
3. Display your current user, role, and warehouse. Query DEMO_DB.SCOTT.DEPT and verify the four department rows.
4. Exit the interactive session and run **12-SnowflakeCLI-Lab.sql** using student_lab.
5. Export only the department query results to a local file named **departments.csv**. Open the file and verify the column headings and four department rows.

CSV hint: run **snow sql --help**. Look for **-q**, **--format CSV**, and **--silent**. Your terminal's > operator saves output to a file. Run the export outside the interactive SQL session. Export one SELECT query, not the entire lab script. An existing file with the same name is overwritten.

On Windows, inspect the file with **notepad departments.csv**. No answer file or submission is required; verify your results with the instructor.

Finish

Keep the training connection for the Internal Stages lab. Close the terminal when finished to end session-scoped password variables. This lab creates no database objects, so no SQL cleanup is needed.
